## Markov-Dubins problem with free terminal direction

*Find the shortest path between two points  $u, v$  in a space  $X$ , given a prescribed initial direction  $U$  and prescribed minimal turning radius  $R > 0$ .*

- (Markov, 1889): Formulated the problem with  $X = \mathbb{R}^2$  in a little-known paper
- Practical application: How can an existing length of railroad track be joined to a given destination, using as little new track as possible?

- Initial heading and position fixed; direction at the destination is not specified
- Minimal turning radius was needed to prevent derailment
- Problem seems to have been largely forgotten until the 1950s

## ■ Edges of $\mathcal{T}$

- A set  $\mathcal{G}$  of pairs of inverse elementary moves is specified.

Such a pair is called a **generator**.

- In our example, each elementary move slides one robot on its track to an unoccupied adjacent vertex.

A generator  $\varphi$  is defined by the following pair of moves:

If vertex 1 is occupied by  $\bullet$  and vertex 2 is unoccupied, move  $\bullet$  to vertex 2.

If vertex 2 is occupied by  $\bullet$  and vertex 1 is unoccupied, move  $\bullet$  to vertex 1.

# Edges of the transition graph

## ■ Edges of $\mathcal{T}$

- Each generator  $\varphi$  is represented as a pair of labelings of a subset  $\mathcal{S}$  of  $\text{Vert}(\mathcal{W})$ . To **apply**  $\varphi$  to a state  $u$  means to redefine  $u$  on  $\mathcal{S}$ , obtaining a new labeling

$$\varphi[u] : \{1, 2, 3, 4, 5, 6, 7\} \rightarrow \{\circ, \bullet, \bullet\}.$$

- Two states  $u, v \in \text{Vert}(\mathcal{T})$  are joined by an edge in  $\mathcal{T}$  if some generator  $\varphi \in \mathcal{G}$  toggles the system between states  $u$  and  $v$ .

- A collection of states that is closed under the application of all generators is an **(abstract) reconfigurable system**.

# Graph-theoretic formulation of the reconfiguration problem

## Graph-theoretic formulation of the reconfiguration problem

- 1 Discretize the two tracks, subdividing each into finitely many edges. The result is the **workspace graph**  $\mathcal{W}$ .
- 2 Construct the transition graph  $\mathcal{T}$ .
- 3 Find the shortest path from an initial state  $u \in \text{Vert}(\mathcal{T})$  to the goal state  $v \in \text{Vert}(\mathcal{T})$ .

Such a path corresponds to a sequence of elementary moves that reconfigures the system from state  $u$  to state  $v$ .

### *Drawback of graph-theoretical formulation*

- A shortest path in  $\mathcal{T}$  need not be an efficient reconfiguration strategy
- Transition graph does not encode information about which moves can be applied concurrently

*Use cubes to encode concurrency*

- We say that  $k$  generators **commute** at a state  $u$  if they can be applied to  $u$  simultaneously, and if the resulting configuration is independent of the order in which they are applied.
- Wherever the 1-skeleton  $Q^{(1)}$  of a  $k$ -cube appears in  $\mathcal{T}$ , attach a  $k$ -cube if for each vertex  $u$  of  $Q^{(1)}$ , the generators corresponding to the edges incident with  $u$  commute at  $u$ .

By attaching cubes to the transition graph as described, the configuration space of a reconfigurable system is realized as a cube complex called the **state complex**.

# The state complex of a reconfigurable system

State complex for a metamorphic robotic system

composed of pivoting hexagonal tiles (Ghrist-Peterson, 2007)

- Interior points of a cube are intermediate stages of a transition between states.
- A path along a  $k$ -cube's diagonal represents the simultaneous application of the  $k$  commuting generators corresponding to the  $k$  parallelism classes of the cube's edges.
- A path from  $u$  to  $v$  in the state complex determines a strategy for reconfiguring the system from state  $u$  to state  $v$ .

# Fault tolerance

But in a real world environment, changing circumstances in the physical workspace may intervene to make a reconfiguration strategy that is already in progress impossible to complete.

- Suppose a goal state has been prescribed, but an obstruction prevents us from attaining it. A new goal state in the state complex may then be prescribed.
- It is inefficient to bring the system to a halt whenever a new strategy is prescribed, and impractical to instantaneously follow the new strategy without stopping.
- We therefore seek a solution to the problem of finding a shortest path in the state complex with a given initial direction.
- In order to limit the stress placed on the system's physical components, we impose a bound on the path's curvature.

Before we give a formal statement of our central problem, we will briefly review the definition of a *nonpositively curved geodesic space* . . .

(LEFT:) A geodesic triangle  $\Delta xyz$  in a square complex, and (RIGHT:) a comparison triangle in  $\mathbb{R}^2$  for  $\Delta xyz$

A metric space  $(X, d)$  is a **geodesic space** if every  $x, y \in X$  can be joined by a path in  $X$  of length  $\ell = d(x, y)$ , called a **geodesic**.

- A geodesic from  $x$  to  $y$  will be denoted by  $[xy]$ .

Let  $x, y, z$  be three distinct points in a geodesic space. Then

$$\Delta xyz := [xy] \cup [yz] \cup [zx]$$

is a **geodesic triangle**, and a **comparison triangle**  $\Delta x'y'z'$  for  $\Delta xyz$  is a triangle in the Euclidean plane with corresponding sides equal in length.

# Nonpositive curvature

## Thin triangles

A geodesic triangle  $\Delta xyz$  is **thin** if the distance between any two points on  $\Delta xyz$  is no larger than the distance between the corresponding points on a comparison triangle:

$$d(p, q) \leq d(p', q').$$

A geodesic space  $X$  is

- **nonpositively curved (NPC)** at a point  $w$  if all geodesic triangles sufficiently near  $w$  are thin,
- **nonpositively curved** if  $X$  is nonpositively curved at every point,
- **CAT(0)** if  $X$  is simply connected and nonpositively curved.

- (Dubins, 1957): For certain choices of  $\kappa > 0$ ,  $U \in S^1$ , and  $u, v \in \mathbb{R}^2$ , the collection  $\mathcal{D}$  of twice-differentiable unit-speed paths  $\gamma : [a, b_\gamma] \rightarrow \mathbb{R}^2$  with

$$\gamma(a) = u, \quad \gamma'(a) = U, \quad \gamma(b_\gamma) = v, \quad |\gamma''| \leq \kappa$$

does not contain an element of minimum length.

But for any choice of  $\kappa > 0$ ,  $u, U$ , and  $v$ , there exists a  $C^1$  and piecewise twice-differentiable path  $\beta$  with length

$$\ell(\beta) = \inf_{c \in \mathcal{D}} \ell(c).$$

Example:

Pick

$$\kappa = 1, \quad u = (0, 0), \quad U = (0, 1), \quad v = (3, 1),$$

and let  $\beta$  be the shortest CL path in  $\mathbb{R}^2$  satisfying these boundary conditions and curvature bound.

- A **CL path** is the  $C^1$  concatenation of a circular arc and a line segment.

Small Block condition

- (Dubins, 1957): For certain choices of  $\kappa > 0$ ,  $U \in S^1$ , and  $u, v \in \mathbb{R}^2$ , the collection  $\mathcal{D}$  of twice-differentiable unit-speed paths  $\gamma : [a, b_\gamma] \rightarrow \mathbb{R}^2$  with

$$\gamma(a) = u, \quad \gamma'(a) = U, \quad \gamma(b_\gamma) = v, \quad |\gamma''| \leq \kappa$$

does not contain an element of minimum length.

But for any choice of  $\kappa > 0$ ,  $u, U$ , and  $v$ , there exists a  $C^1$  and piecewise twice-differentiable path  $\beta$  with length

$$\ell(\beta) = \inf_{c \in \mathcal{D}} \ell(c).$$

Example:

Then

- Every  $\gamma \in \mathcal{D}$  has  $\ell(\gamma) > \ell(\beta)$ .
- For any  $\varepsilon > 0$ , there exists  $\gamma \in \mathcal{D}$  with  $\ell(\beta) < \ell(\gamma) < \ell(\beta) + \varepsilon$ .

# Sufficient collection of paths

How should we define “admissible”?

- $C^1$  in local coordinates, with  $\kappa$ -Lipschitz derivative
  - Rules out abrupt changes in direction which would put stress on moving parts of the system
  - Permits CL paths
  - Can use Dubins’ characterization of optimal paths to describe optimal paths contained in a cell

We now define *piecewise-Lipschitz differentiability* for curves in a cube complex.

# Piecewise Lipschitz-differentiable curves in a cube complex

Let  $\gamma : [a, b] \rightarrow X$  be a path in a cube complex  $X$ , and let

$$a = t_1 < t_2 < \dots < t_m = b$$

be a partition of  $[a, b]$ . A sequence  $(Q_k)_{k=1}^{m-1}$  of cells in  $X$  is a **cube path for  $\gamma$  with breakpoints**  $(t_k)_{k=1}^m$  if

$$\gamma([t_k, t_{k+1}]) \subset Q_k, \quad Q_k \not\subset Q_{k+1}, \quad Q_k \not\supset Q_{k+1}.$$

A cube path for a curve  $\gamma : [a, \infty) \rightarrow X$  is defined similarly, taking  $m = \infty$ .

We call each

$$\gamma_k := \gamma|_{[t_k, t_{k+1}]}$$

a **segment** of  $\gamma$ .

- Note  $\gamma(t_k) \in Q_{k-1} \cap Q_k$
- **edgewise** cube path:  
each  $Q_k \cap Q_{k+1}$  is an edge
- **locally monotone square** path:  
 $Q_{k-1} \cap Q_k \neq Q_k \cap Q_{k+1}$   
for each suitable  $k$ , and  
 $\dim Q_k = 2$  for all  $k$

# Piecewise Lipschitz-differentiable curves in a cube complex

A path in  $\mathbb{R}^N$  is  $\kappa\text{-}\mathcal{C}^{1,1}$  (or  $\kappa$ -Lipschitz differentiable) if its derivative exists and is  $\kappa$ -Lipschitz.

Let  $X$  be a cube complex, let  $\kappa > 0$ , and let  $M \in \mathbb{N}$  ( $M \geq 2$ ).  
A path

$$\gamma : [a, b] \rightarrow X$$

is  $\kappa\text{-}\mathcal{C}^{1,1}(M)$  (or  $\kappa$ -Lipschitz differentiable with at most  $M$  breakpoints) if there exists a cube path  $(Q_k)_{k=1}^{m-1}$  for  $\gamma$  with breakpoints

$$a = t_1 < t_2 < \dots < t_m = b \quad (m \leq M)$$

such that each segment

$$\gamma_k : [t_k, t_{k+1}] \rightarrow Q_k$$

is  $\kappa\text{-}\mathcal{C}^{1,1}$  in coordinates.

# Length-minimal element of $\mathcal{C}(\kappa, M, u, v, U)$

Let  $X$  be a nonpositively curved locally finite cube complex. Fix

- $u, v$  in  $X$  such that  $u \neq v$ ,
- a unit tangent vector  $U$  to  $p(C_\lambda)$  at  $p_\lambda(u)$  for some  $\lambda$ ,
- $\kappa > 0$ , and
- $M \in \mathbb{N}$  ( $n \geq 2$ ).

Let

$$\mathcal{C}(\kappa, M, u, v, U)$$

be the set of  $\kappa$ - $\mathcal{C}^{1,1}(M)$  unit-speed paths  $\gamma : [a, b_\gamma] \rightarrow X$  with

$$\gamma(a) = u, \quad \gamma(b_\gamma) = v, \quad \gamma'(a) = U.$$

## Theorem

*If  $\mathcal{C} = \mathcal{C}(\kappa, M, u, v, U)$  is nonempty, then  $\mathcal{C}$  contains a path  $\beta$  of minimal length among all paths in  $\mathcal{C}$ .*

# Smoothness at breakpoints

The proof of the theorem uses only advanced calculus and Arzela-Ascoli. We begin with a sequence of admissible paths  $\gamma_n \in \mathcal{C}$  such that

$$\ell(\gamma_n) \searrow \inf_{c \in \mathcal{C}} \ell(c),$$

and repeatedly pass to subsequences so that

- there is a single cube path  $(Q_k)_{k=1}^{\infty}$  with breakpoints  $(t_k)_{k=1}^{\infty}$  for all  $\gamma_n$ , and
- for each  $k$ , each of  $(\gamma_n|_{[t_k, t_{k+1}]})_{n=1}^{\infty}, (\gamma'_n|_{[t_k, t_{k+1}]})_{n=1}^{\infty}$  converge.

We then show that the uniform limit  $\gamma$  of the  $\gamma_n$  is in  $\mathcal{C}$ .

We then show that the uniform limit  $\gamma$  of the  $\gamma_n$  is in  $\mathcal{C}$ .

More is needed to prove the existence of a solution to the Markov-Dubins problem: we want our paths to have zero **turning angle**

$$\pi - \angle(\gamma_k^-, \gamma_k^+) \in [0, \pi], \quad \gamma_k^- := \overline{\gamma|_{(t_k - \varepsilon, t_k]}}, \quad \gamma_k^+ := \gamma|_{[t_k, t_k + \varepsilon)},$$

for each interior breakpoint  $t_k$ .

- The property of having zero turning angle at breakpoints is preserved when passing to the limit.
- We carry out the same argument as for the previous theorem, but this time, we'll require that admissible paths have zero turning angle at interior breakpoints.

## Some technical issues and their solutions:

$\lim_{n \rightarrow \infty} \ell(\gamma_k^n) \neq 0$	Construct geodesics with same directions as subarcs ( <i>above fig.</i> ) and use u.s.c. of $\angle$
$\lim_{n \rightarrow \infty} \ell(\gamma_{k+1}^n) \neq 0$	
$\lim_{n \rightarrow \infty} \ell(\gamma_1^n * \dots * \gamma_k^n) = 0$	Reparametrize and delete $(Q_i)_{i=1}^k$ from cube path
$\lim_{n \rightarrow \infty} \ell(\gamma_k^n) \neq 0$	Total curvature is lower semicontinuous, $\therefore \tau_k + \tau_{k+2} = \lim_n \tau^n[t_k, t_{k+3}] \geq \tau[t_k, t_{k+3}]$ $= \tau_k + \angle(\tilde{\gamma}_k, \gamma_{k+2}) + \tau_{k+2}, \quad \therefore \angle(\tilde{\gamma}_k, \gamma_{k+2}) = 0.$
$\lim_{n \rightarrow \infty} \ell(\gamma_{k+1}^n) = 0$	
$\lim_{n \rightarrow \infty} \ell(\gamma_{k+2}^n) \neq 0$	
$\lim_{n \rightarrow \infty} \ell(\gamma_k^n * \dots * \gamma_m^n) = 0$	Reparametrize and delete $(Q_i)_{i=k}^{m-1}$ from cube path

Here  $\gamma_k^n = \gamma_n|_{[t_k, t_{k+1}]}$ .

# Existence result for Markov-Dubins problem with free terminal direction

We say a  $\kappa\text{-}\mathcal{C}^{1,1}(M)$  path  $\gamma$  is **smooth at breakpoints** if there exists a cube path  $(Q_k)_{k=1}^{m-1}$  ( $m \leq M$ ) for  $\gamma$  with breakpoints  $(t_k)_{k=1}^m$  such that  $\gamma$  has zero turning angle at  $\gamma(t_k)$  for  $1 < k < m$ .

For  $\kappa, M, u, v, U$  as above, write

$$\begin{aligned}\mathcal{C}_0 &= \mathcal{C}_0(\kappa, M, u, v, U) \\ &= \{\gamma \in \mathcal{C}(\kappa, M, u, v, U) : \gamma \text{ is smooth at breakpoints}\}.\end{aligned}$$

## Theorem

At the instant when the new goal state is prescribed, we have a Markov-Dubins problem with prescribed initial position, initial direction, and terminal position.

To find CL paths in a NPC square complex, we will need an algorithm for finding geodesic paths.

# Chepoi-Maftuleac unfolding

Chepoi and Maftuleac's algorithm for finding geodesics depends on the following result.

## Theorem (Chepoi-Maftuleac, 2012)

*The geodesic between two points  $u, v$  of a  $CAT(0)$  square complex  $X$  lies in a subcomplex  $K$  of  $X$  which is isometric to a monotone planar polygon. Moreover,  $K$  depends only on the choice of 2-cells containing  $u$  and  $v$ .*

- This result reduces the problem of finding shortest paths in  $X$  to that of finding shortest paths in planar polygons: no shortcut from  $u$  to  $v$  is possible by leaving  $K$ .

Here, a polygon  $P$  is **monotone** if every axis-aligned line segment with endpoints in  $P$  is contained in  $P$ .

Many algorithms for finding shortest paths in a monotone polygon exist. We use the classic “funnel algorithm” of Lee and Preparata.

- A monotone polygon  $P$  can be triangulated by edges  $E_i$  with endpoints on the boundary of  $P$
- The dual graph of the triangulation is a path
- The path determines an ordering of edges  $E_i$  that starts with the base of a triangle containing the initial point  $u$  (green dot) and ends with the base of a triangle containing the terminal point  $v$  (red dot)

# Inaccessibility and properness

We can identify regions of the  $d$ -plane which are inaccessible by a CL path  $\gamma$  if the initial arc of  $\gamma$  is a subarc of a *proper ray*.

- A map is **proper** if the preimage of every compact set is compact.
- A ray  $\gamma : [a, \infty) \rightarrow X$  **eventually never returns** to a subset  $S$  of  $X$  if for some  $t > a$ ,

$$S \cap \gamma([t, \infty)) = \emptyset,$$

and  $\gamma(s) \in S$  for some  $s < t$ .

- A ray is proper  $\iff$  it eventually never returns to each cell it meets.

- *Counterexample:* If the edges  $E$  and  $E'$  in the definition are adjacent sides of some square cell  $Q$ , then  $H$  and  $H'$  must meet in  $Q$ .

# Stacks

A **stack** in a cube complex  $X$  is a sequence  $(H_n)_{n=1}^{\infty}$  of successively osculating hyperplanes,  $H_n \cap H_{n+1}$ .

We would like the hyperplanes in a stack to satisfy two properties:

- Each hyperplane should divide the space (which in our case, is homeomorphic to  $\mathbb{R}^2$ ) into two disjoint halfspaces.
- The hyperplanes should define two sequences of nested halfspaces, a “backward” sequence nested from smaller to larger, and a “forward” sequence nested from larger to smaller.

If the hyperplanes of a stack satisfy these two properties, we call it an *oriented stack*.

## Lemma

*Let  $\mathcal{H} = (H_n)_{n=1}^{\infty}$  be a stack of hyperplanes in  $\mathcal{X}_d$  ( $d \geq 4$ ). Then  $\mathcal{H}$  can be oriented.*

*Proof (sketch).*  $\mathcal{X}_d$  is the Davis complex of a RACS, hence a CAT(0) cube complex, hence A-special. Then osculating hyperplanes do not intersect. The complement in  $\mathcal{X}_d$  of each hyperplane has two components, and by a connectedness argument,  $\mathcal{H}$  can be oriented. □

# Showing a ray is proper using osculating hyperplanes

## Lemma

A ray  $\gamma : [a, \infty) \rightarrow \mathcal{X}_d$  is proper if for some

$$a \leq t_1 < t_2 < t_3 < \dots$$

and some oriented stack  $(H_n)_{n=1}^{\infty}$  of hyperplanes, we have

$$\gamma([t_n, \infty)) \subset H_n^+.$$

This Lemma gives a sufficient condition for a ray to be proper.

- The condition is simple, but impractical
- Even for a geodesic path, finding the breakpoints can only be done iteratively
- (A-O-S): The breakpoints of a geodesic have no closed form analytic description
- We need a systematic procedure for building an infinite stack in the  $d$ -plane
- Rather than focusing on the intersection of the ray with infinitely many hyperplanes, we analyze the square path for the ray, which has an easily described combinatorial structure

# Finite stacks in $\mathbb{E}^2$

- Transfer a square path  $Q = (Q_k)_{k=1}^\infty$  for  $\gamma$  in  $\mathcal{X}_d$  to  $\mathbb{E}^2$  by continuation, keeping track of cell structure.
- The resulting ray  $\check{\gamma}$  is a parametrized circle. Subdivide  $\check{\gamma}$  into four arcs, each of which is properly segmented by a finite stack in  $\mathbb{E}^2$ .

---

We will transfer each of the four finite stacks into  $\mathcal{X}_d$ .

# Transferring a stack

- Transfer a square path  $\mathcal{Q} = (Q_k)_{k=1}^{\infty}$  for  $\gamma$  in  $\mathcal{X}_d$  to  $\mathbb{E}^2$  by continuation, keeping track of cell structure.
- The resulting ray  $\check{\gamma}$  is a parametrized circle. Subdivide  $\check{\gamma}$  into four arcs, each of which is properly segmented by a finite stack in  $\mathbb{E}^2$ .
- Transfer each stack in  $\mathbb{E}^2$  to  $\mathcal{X}_d$ .

A *scaffold* is the minimal data needed to carry out the transfer of a stack between two square complexes in a controlled way.

It consists of a sequence of pairs of adjacent edges, respectively dual to each pair of successive hyperplanes in a stack.

# Infinite stack in $\mathcal{X}_d$

- Transfer a square path  $Q = (Q_k)_{k=1}^\infty$  for  $\gamma$  in  $\mathcal{X}_d$  to  $\mathbb{E}^2$  by continuation, keeping track of cell structure.
- The resulting ray  $\check{\gamma}$  is a parametrized circle. Subdivide  $\check{\gamma}$  into four arcs, each of which is properly segmented by a finite stack in  $\mathbb{E}^2$ .
- Transfer each stack in  $\mathbb{E}^2$  to  $\mathcal{X}_d$ .
- Assemble the finite stacks in  $\mathcal{X}_d$  into an infinite sequence of successively osculating hyperplanes.

Finally, we assemble the sequence of finite stacks in the  $d$ -plane, obtained from the four finite stacks in  $\mathbb{E}^2$ , into a single infinite stack with respect to which the given square path in  $\mathcal{X}_d$  is properly segmented.

Using the nonpositive curvature of  $\mathcal{X}_d$ , we can assemble the finite stacks into a single infinite stack if. . .

```
isElbowJoint[squareCenter_, indexInSquarePath_] :=  
(angle @@ neighborCenters[squareCenter, indexInSquarePath]) ==  $\pi / 2$ ;
```

... we can find four suitable "reflex angles" in the interior component of the boundary of the square path in  $\mathbb{E}^2$ .

This can always be done if the carrier of the circle in  $\mathbb{E}^2$  is an annulus.

# Sufficient condition for a ray in $\mathcal{X}_d^*$ of constant curvature to be proper

## Annulus Condition

Let  $\gamma : [a, \infty) \rightarrow \mathcal{X}_d^* = \mathcal{X}_d \setminus \text{Vert}(\mathcal{X}_d)$  ( $d \geq 5$ ) be a curve of constant curvature  $\kappa > 0$ . Let  $\mathcal{U}$  be an unfolding of a locally monotone edgewise square path  $\mathcal{Q}$  in  $\mathcal{X}_d$  for  $\gamma$ . Let  $\varphi : \mathcal{U} \rightarrow \mathbb{E}^2$  be a cellular local isometry.

If  $\text{Image } \varphi \stackrel{\text{homeo}}{\approx} S^1 \times I$ , then  $\gamma$  is a proper ray.
